WEB-DEVELOPMENT ACTIVITY-BASED-LEARNING

PROJECT REPORT

Prepared as part of the Web Development Activity-Based Learning assignment.

STUDENT DETAILS

Name: Pulugundla Thanusha
Roll Number: 26001107
Branch: CSE (AI & ML)
Section: CSM-4

SELECTED CASE STUDIES

01. Travel Agency
Design and development of a webpage presenting travel destinations and travel-related information.

02. Hotel Reservation
Design and development of a webpage presenting hotel information and reservation options.

03. Movie Review and Rating
Design and development of a webpage displaying movie details, reviews, and ratings.

Technologies Used: HTML5 and CSS3

CASE STUDY 1: TRAVEL AGENCY WEBSITE — WANDERLY

1. Introduction

Wanderly is a travel agency website designed to help users explore travel destinations and discover holiday packages. It presents destination information, package details, prices, and a trip enquiry form in an attractive and organized layout. The website is developed using HTML5 and CSS3.

2. Objectives

- To design an attractive and user-friendly travel website.
- To display popular travel destinations and their descriptions.
- To present travel packages, durations, and prices.
- To provide navigation links between different sections.
- To create a trip enquiry form for collecting basic travel preferences.

3. Technologies Used

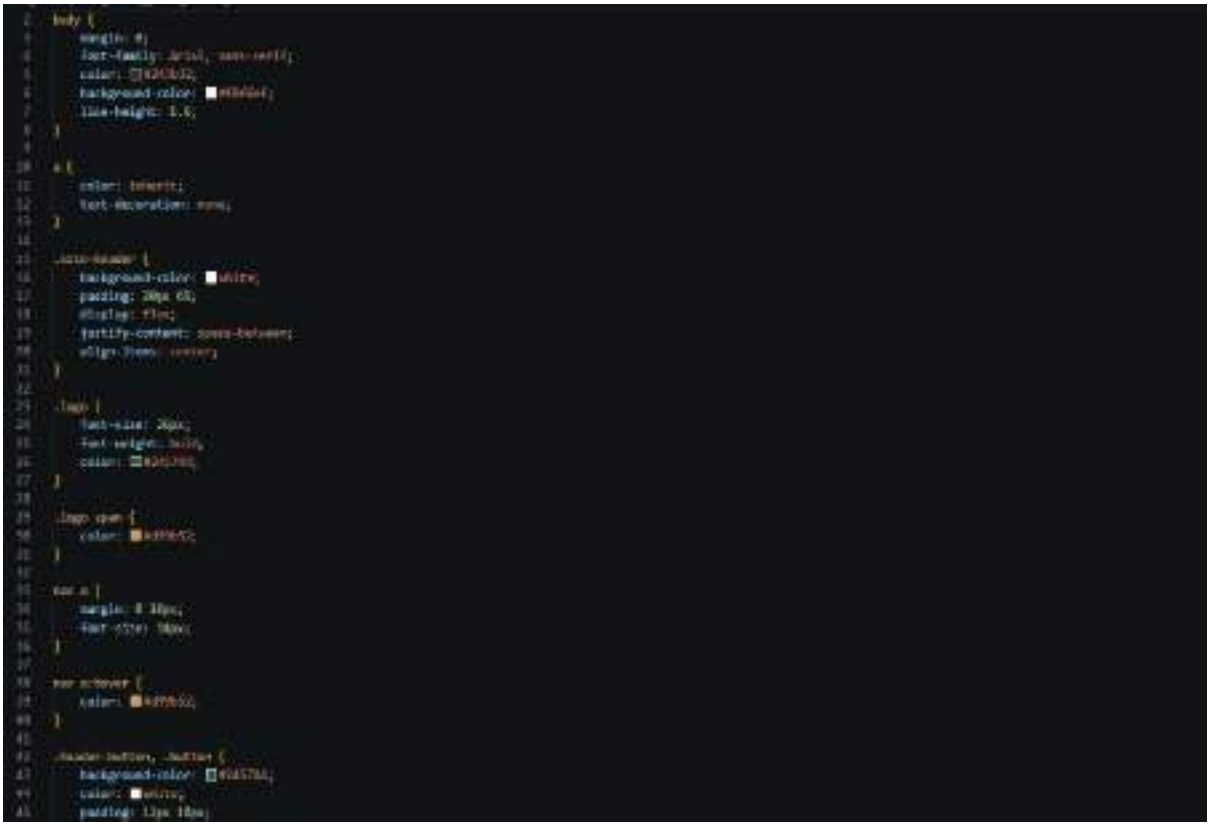

- HTML5: Structures the webpage using headings, sections, links, cards, and form elements.
- CSS3: Controls colours, typography, spacing, backgrounds, and page layout.
- Visual Studio Code: Used to write and edit the code.
- Web Browser: Used to run and test the website.

4. Website Features

1. Header and Navigation: Displays the Wanderly logo and navigation links.
2. Hero Section: Introduces the website with a heading, description, and call-to-action link.
3. Introduction Section: Presents the website's travel-planning concept.
4. Destination Cards: Displays Bali, the Swiss Alps, and the Amalfi Coast with descriptions.
5. Travel Packages: Displays package names, durations, destinations, and prices.
6. Trip Enquiry Form: Allows users to enter their name, select a destination, choose a travel month, and specify the number of travellers.
7. Footer: Displays the website slogan and copyright information.

Input images:

5. HTML Code Explanation

The HTML document begins with <!DOCTYPE html>, which declares the document as HTML5. The <head> section contains the page title, character encoding, viewport settings, and a link to the external CSS file.

The <body> contains the visible webpage content. The <header> and <nav> elements organize the logo and navigation links. The <main> element contains the major sections of the website.

The <section> elements organize the introduction, destinations, packages, and contact form. The <article> elements represent individual destination cards and travel packages. The <form> element contains labels, text inputs, dropdown lists, and a submit button.

The <footer> displays the closing slogan and copyright information. The HTML uses IDs and hyperlinks to connect the navigation menu to specific sections of the same page.

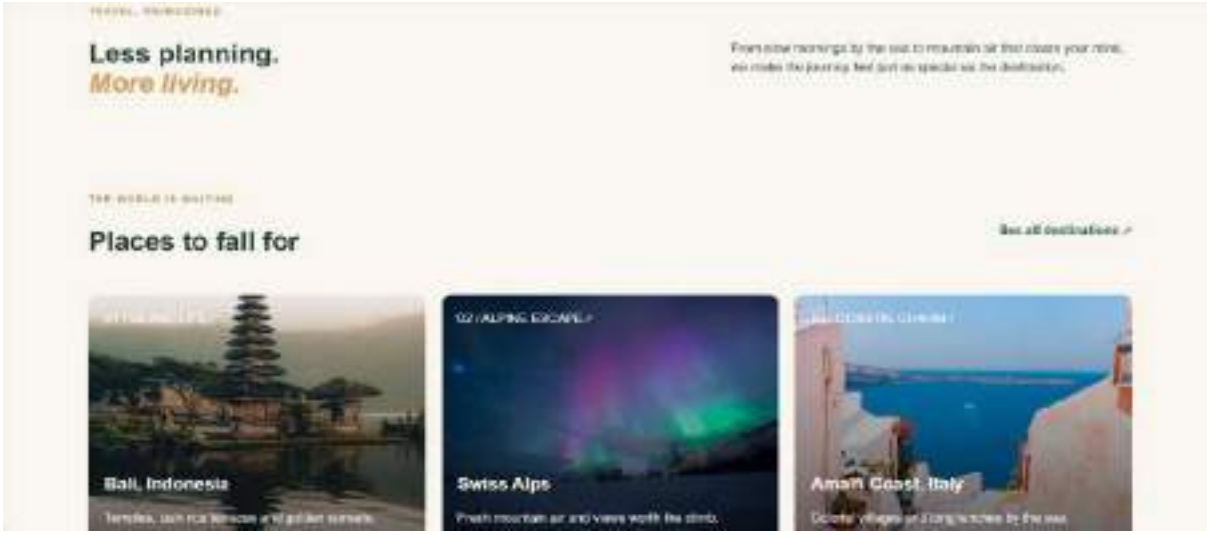

6. CSS Code Explanation

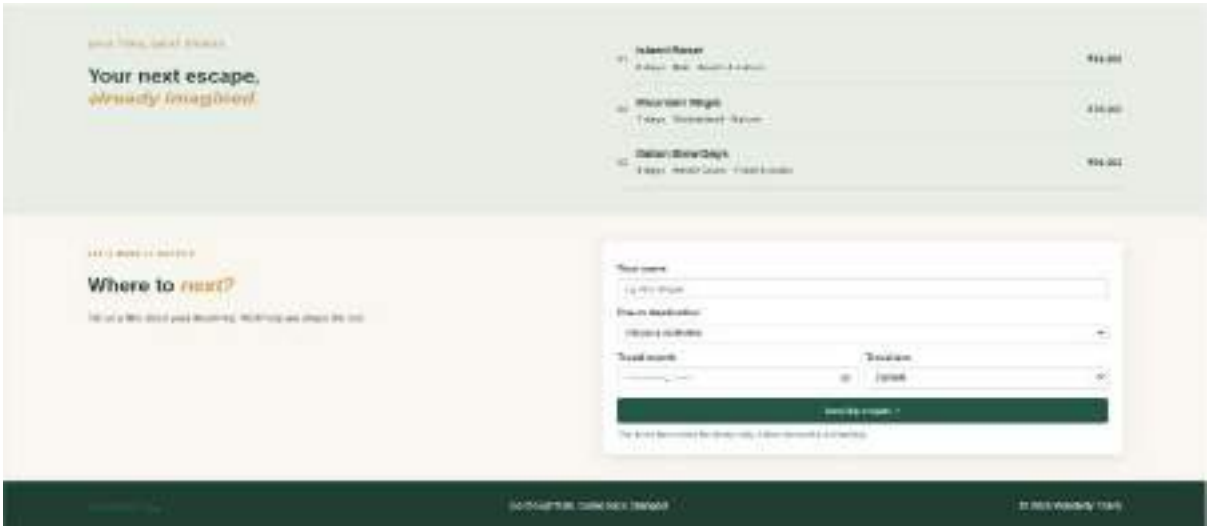

The external stylesheet tourism.css controls the visual appearance of the website. Classes such as site-header, travel-hero, destination-grid, destination-card, package-band, and trip-form allow different parts of the webpage to be styled separately.

CSS is used to arrange content, style headings and buttons, control spacing, and create an attractive layout. The destination-specific classes bali, swiss, and amalfi allow individual cards to have different styling.

Output images:

7. Output Description

The output is a travel agency webpage containing a navigation header, introductory hero section, destination cards, holiday packages, a trip enquiry form, and a footer. Internal navigation links help visitors move between sections. The form is a demonstration interface and is not connected to a real booking system.

8. Conclusion

The Wanderly project demonstrates how HTML5 and CSS3 can be used to create an organized and visually appealing travel website. It provides practical experience in semantic HTML, hyperlinks, page sections, form elements, and external CSS styling.

CASE STUDY 2: HOTEL RESERVATION WEBSITE

1. Introduction

The Hotel Reservation Website is designed to present hotel information and help visitors explore accommodation options. It provides a structured interface for displaying relevant hotel details and reservation-related information. The website demonstrates how HTML5 and CSS3 can be used to organize hospitality-related content.

2. Objectives

- To design a clear and user-friendly hotel website.
- To present hotel and accommodation information in an organized manner.
- To provide easy navigation between different sections.
- To display relevant room or hotel details.
- To demonstrate the use of HTML forms and CSS styling where applicable.

3. Technologies Used

- HTML5: Used to structure the webpage and organize its content.
- CSS3: Used to style the page layout, text, colours, spacing, and visual elements.
- Visual Studio Code: Used for writing and editing the source code.
- Web Browser: Used to display and test the website.

4. Website Features

The website's features should be described according to the implemented code. Relevant features may include:

1. Header and Navigation: Organizes the website title or logo and navigation links.
2. Introduction Section: Presents the hotel or accommodation service.
3. Hotel or Room Information: Displays available hotel details, room descriptions, or accommodation options, if implemented.
4. Images and Descriptions: Helps visitors understand the accommodation through visual content, if included.
5. Reservation Form: Provides fields for collecting booking preferences, if implemented.
6. Footer: Displays closing information about the website.

Input images:

5. HTML Code Explanation

The HTML document starts with the HTML5 declaration and contains the <head> and <body> sections. The head section defines the page title, character encoding, viewport settings, and external stylesheet link.

The body contains the visible hotel website content. Semantic elements such as <header>, <nav>, <main>, <section>, and <footer> can be used to organize the page into meaningful parts. Headings and paragraphs present information, while anchor elements provide navigation.

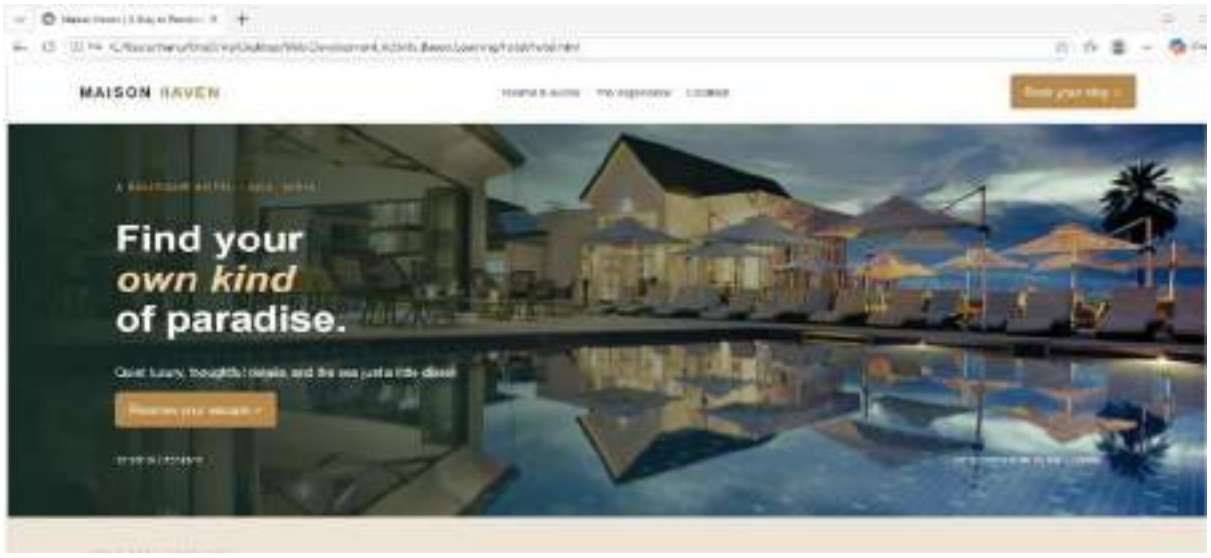

Where a reservation form is implemented, elements such as <form>, <label>, <input>, <select>, and <button> are used to collect user information and booking preferences.

6. CSS Code Explanation

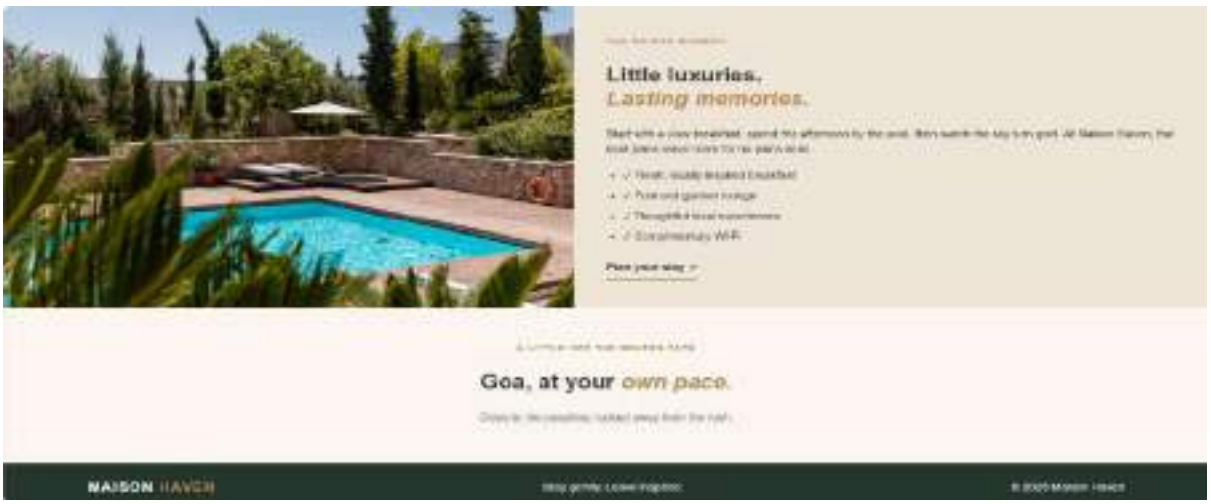

The external CSS file is used to control the website's visual design. CSS rules can style the header, content sections, hotel cards, images, form fields, and buttons. Properties such as color, background-color, padding, margin, and text-align help improve readability and presentation.

CSS classes can be assigned to individual sections so that each part of the website has a consistent appearance.

Output images:

7. Output Description

The output is a hotel-related webpage that organizes accommodation information in a structured layout. Visitors can explore the content and use the interface elements provided by the website. Any reservation-related functionality should be described according to what the actual implementation supports.

8. Conclusion

The Hotel Reservation Website provides practical experience in designing a hospitality-related webpage using HTML5 and CSS3. It helps demonstrate webpage organization, navigation, visual styling, and the use of form elements where applicable.

CASE STUDY 3: MOVIE REVIEW AND RATING WEBSITE

1. Introduction

The Movie Review and Rating Website is designed to present movie-related information in an organized and visually appealing format. It provides a webpage structure for displaying movie details and review-related content. The project demonstrates how HTML5 and CSS3 can be used to create a simple entertainment information website.

2. Objectives

- To design an attractive movie information webpage.
- To organize movie-related content into clear sections.
- To present movie details in a readable format.
- To demonstrate structured content and visual styling.
- To provide a user-friendly interface for viewing movie information and review-related content.

3. Technologies Used

- HTML5: Used to structure movie information, headings, descriptions, links, and other webpage elements.
- CSS3: Used to style the webpage and arrange the movie-related content.
- Visual Studio Code: Used to write and edit the source code.
- Web Browser: Used to run and test the website.

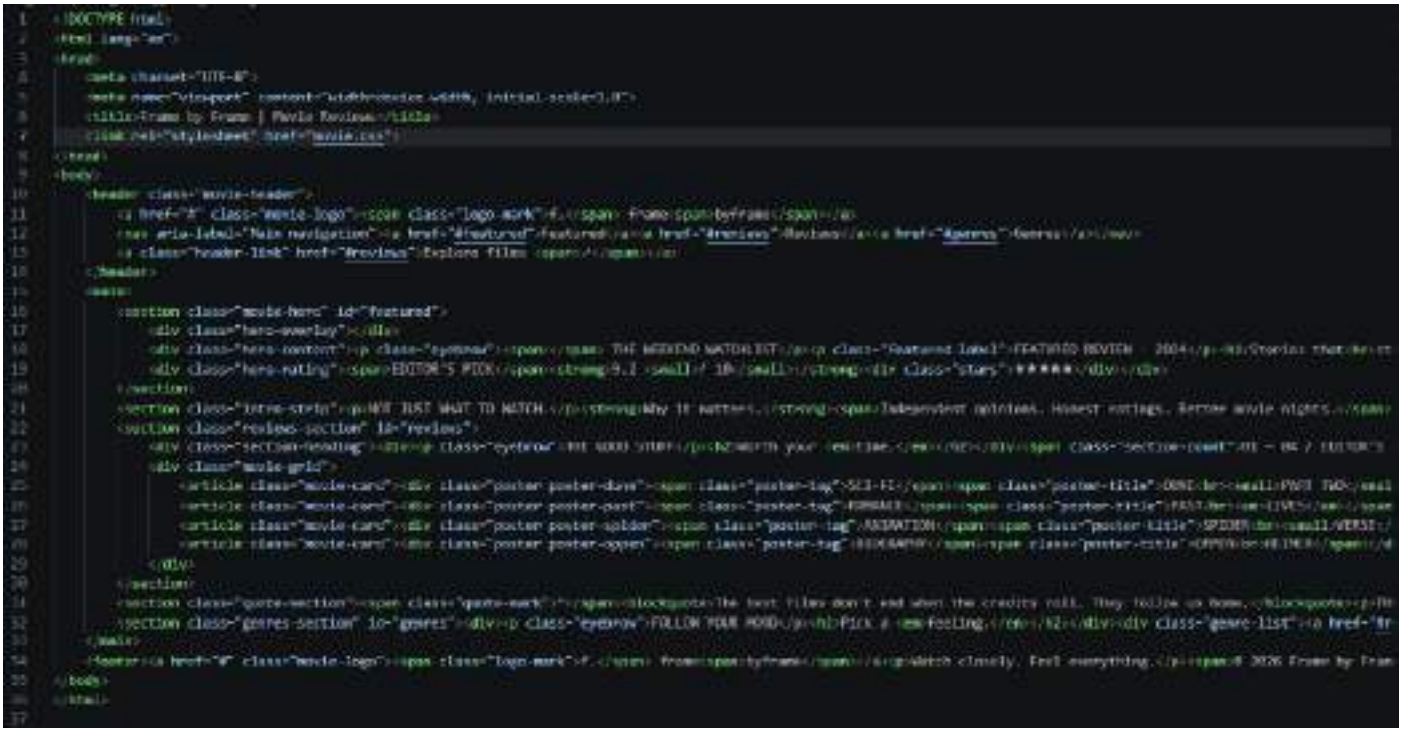

4. Website Features

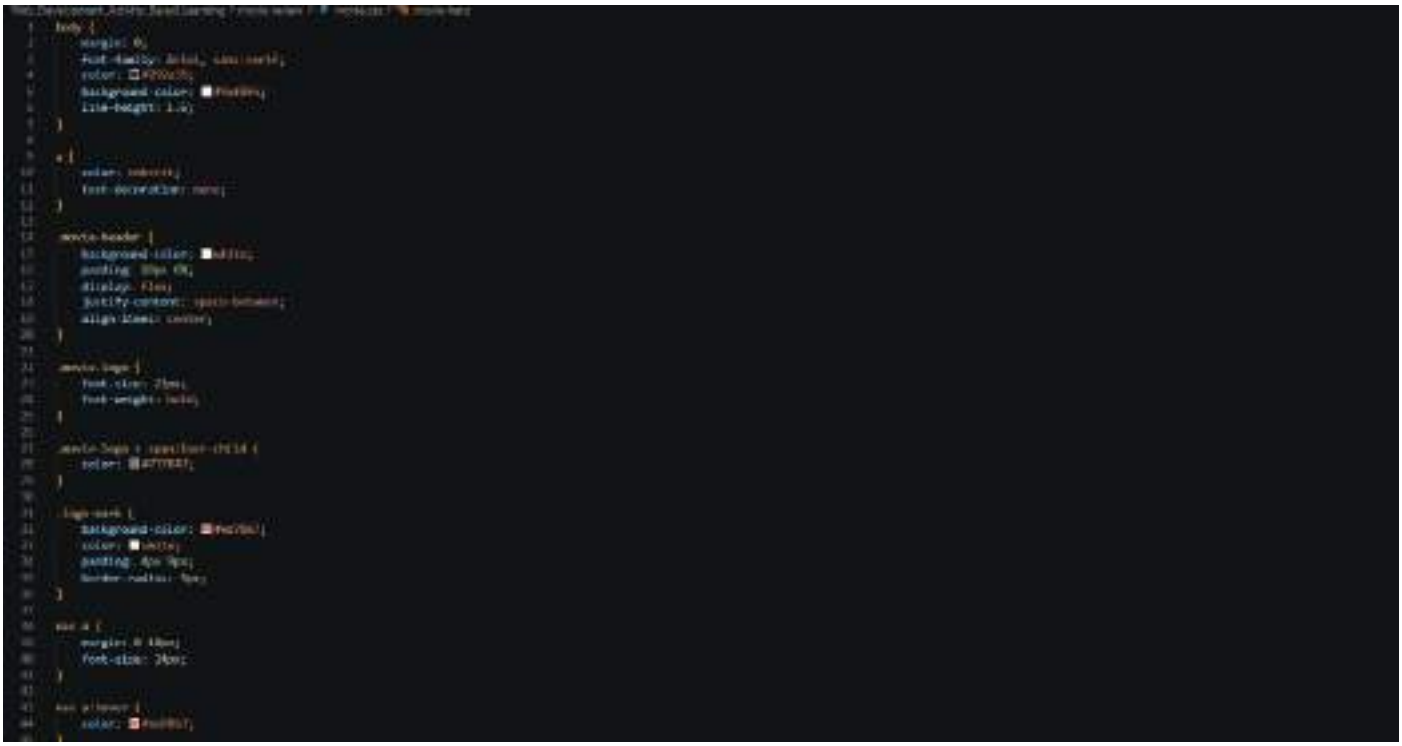

The features below should be retained only if they are present in the actual implementation.

1. Header and Navigation: Displays the website title or logo and navigation links.
2. Introduction Section: Introduces the purpose of the movie website.
3. Movie Display Section: Organizes movie titles and related information.
4. Movie Posters: Uses images to represent movies, if included.
5. Review and Rating Information: Displays review text or rating values, if implemented.
6. Content Layout: Arranges movie information using sections, cards, or other HTML elements.

7. Footer: Provides closing information about the website.

Input images:

5. HTML Code Explanation

The HTML document begins with the HTML5 declaration. The <head> section contains metadata, the webpage title, viewport settings, and the link to the external CSS file.

The <body> contains the visible movie website content. Headings and paragraphs display movie-related information, while sections organize the content into meaningful groups. Anchor elements provide navigation links.

Where movie cards or individual movie entries are used, HTML elements such as or <article> can group the relevant content. The <img> element can display movie posters, and other elements can present titles, descriptions, review text, or ratings.

The HTML structure makes the information easier to read and allows CSS to style different elements independently.

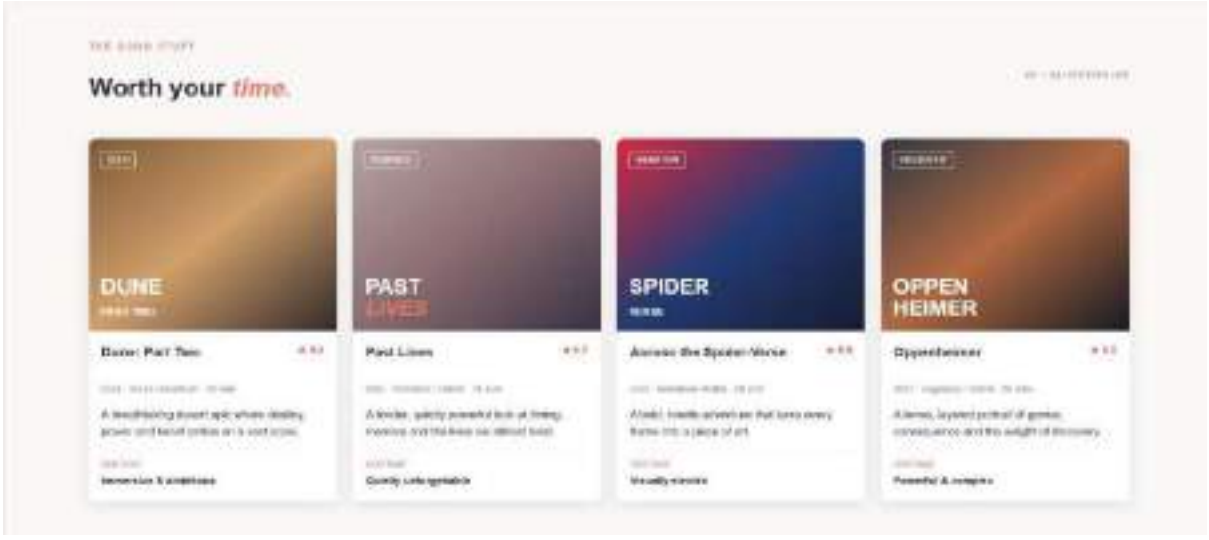

6. CSS Code Explanation

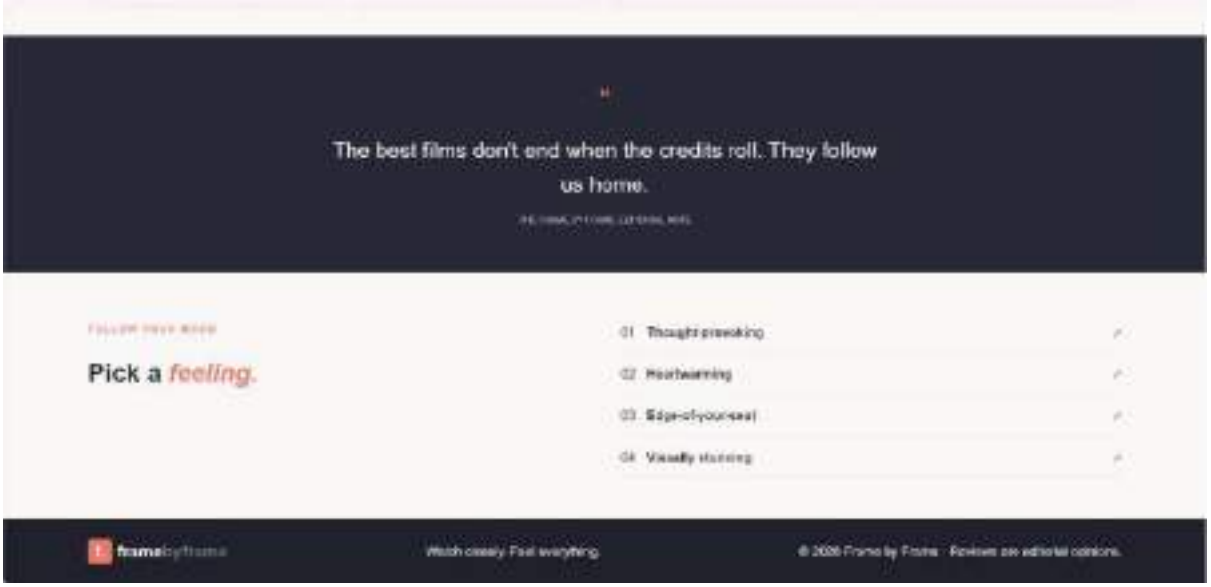

The external CSS stylesheet controls the visual presentation of the movie website. It can define the page background, text colours, fonts, spacing, content alignment, movie cards, and image dimensions.

CSS classes help apply consistent styles to repeated elements. Suitable layouts and spacing improve the readability of movie information and create a visually organized interface.

Output images:

7. Output Description

The output is a movie-related webpage that presents information in a structured layout. Visitors can view the content displayed on the page and use the available navigation elements. Review submission, dynamic ratings, or database functionality should not be claimed unless they are actually implemented.

8. Conclusion

The Movie Review and Rating Website provides practical experience in organizing entertainment-related content using HTML5 and CSS3. It demonstrates webpage structure, content presentation, navigation, and visual styling.

CONCLUSION

The Web Development Activity-Based Learning project helped us understand and apply the fundamental concepts of HTML5 and CSS3 in practical website development.

Three websites were designed and developed based on the selected case studies:

1. **Travel Agency**: Presents travel destinations and travel-related information.
2. **Hotel Reservation:** Displays hotel information and reservation options.
3. **Movie Review and Rating:** Presents movie details, reviews, and ratings.

Through this activity, we gained practical experience in creating webpage structures, applying CSS styles, organizing project files, and designing user-friendly web pages.

This project strengthened our basic web development skills and provided a foundation for learning advanced web technologies.

Future Scope: These websites can be enhanced with JavaScript for interactivity, responsive layouts for different devices, and backend technologies for dynamic features.

Overall, this activity provided valuable hands-on experience in designing and developing websites using HTML and CSS.
